

Thermal In-situ Remediation of the Unsaturated Zone by Steam Injection – Final Presentation –

2002 NATO/CCMS Pilot Study Meeting, 5-10 May 2002, Rome
Hans-Peter Koschitzky, Tilman Theurer, Arne Färber

PREUSSAG

Mühlacker Field Site

2002 NATO/CCMS Pilot Study Meeting Rome

PREUSSAG

Overview

- 1 Mühlacker Field Site
- 2 Objectives of the Pilot Study
- 3 Design and Operation
- 4 New Experiences with Operating Steam Injection under Difficult Conditions
- 5 Comparison Pilot Study / Conventional SVE
- 6 Conclusions

2002 NATO/CCMS Pilot Study Meeting Rome

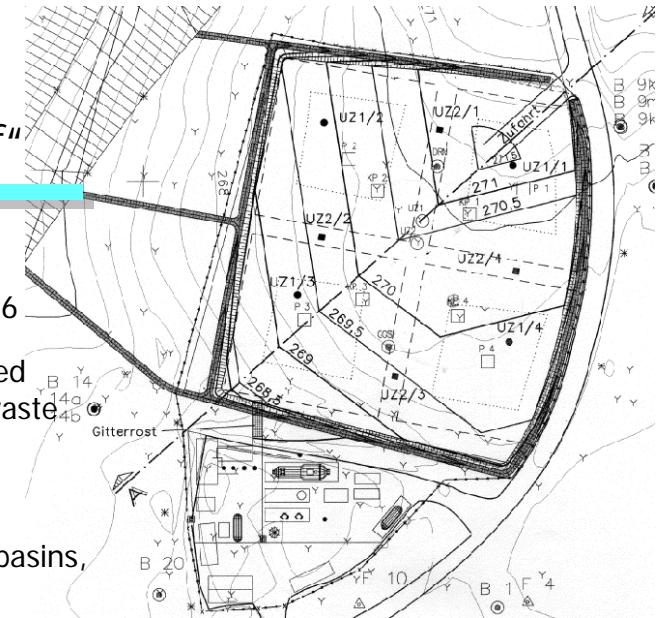

PREUSSAG

Former Landfill „Eckenweiher Hof“

- Waste disposal site, operated 1968 to 1976
- Four earth basins, filled with local industrial waste
- Total volume about 5.400 m³
- No sealing below the basins, no drainage system

Difficult Condition for Steam Injection

Difficult
conditions:

- Low permeability of the subsurface
- Contaminant denser than water

Mühlacker Field Site: Cross Section

- Top layer of clayey loam
- Low permeable marls up to 30 m bgs
- Perched water at soil interface

Site History and Situation

- **CHC = main contamination in the unsaturated zone** below a former hazardous waste disposal site
- **Unsaturated zone**
 - Two low permeable layers 30 m bgs
 - Highly contaminated area 7 – 15 m bgs
- **Technical equipment on site can be used**
 - Conventional soil vapour extraction system
 - Hydraulic P & T system running,
→ safety net for groundwater

Objectives of Pilot Study

- Improve technical feasibility under difficult geological conditions
 - Increase recovery of contaminants
 - Clean-up of target zone
- Reduction of clean-up time and cost
- Optimization of operation
- Gaining data, operational parameters and experiences

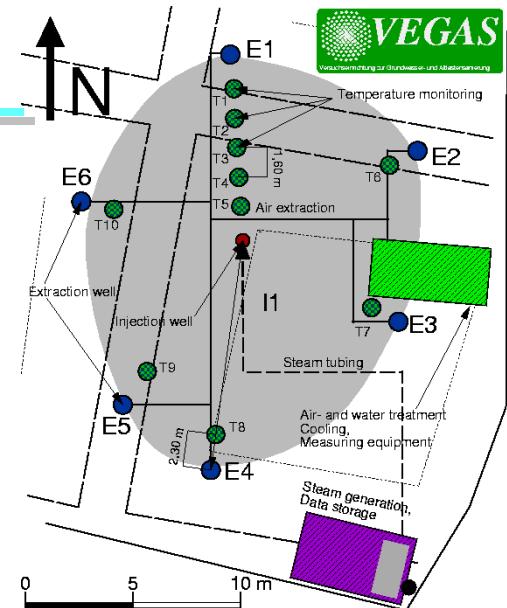

2002 NATO/CCMS Pilot Study Meeting Rome

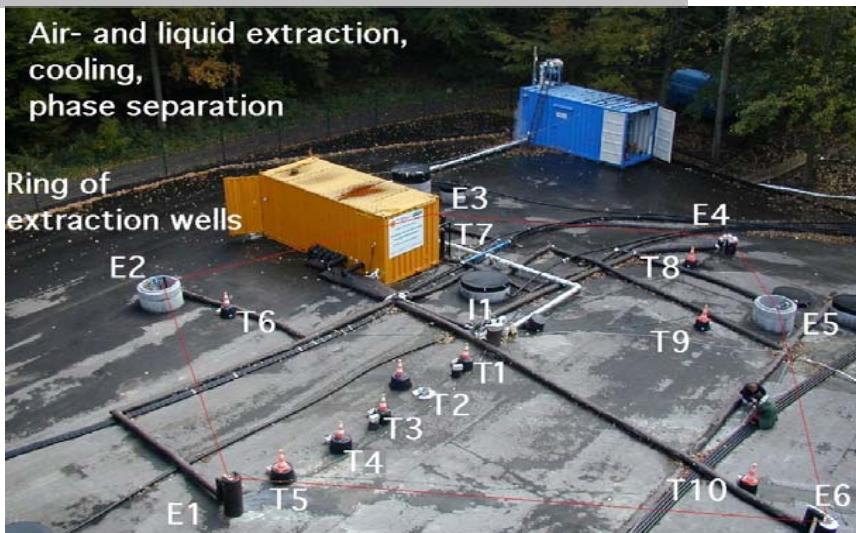

Layout

- One steam injection (I1) well in the center
- Six extraction wells (E1-E6) in a circle ($\varnothing \approx 20$ m)
- Temperature lances down to 15 m bgs
- Technical equipment for SVE, steam injection, etc.

Temperature Distribution – Phase 1

Steam spreads mainly in upper regions

→ Pores blocked by capillary water

VEGAS

PREUSSAG
ZUBLIN
UMWELT
TECHNIK

Temperature Distribution – Phase 2

Steam is distributed over depth

→ Conductive heat transport is used

Temperature Distribution – End of Pilot Study

Subsurface is mainly heated above 80°C

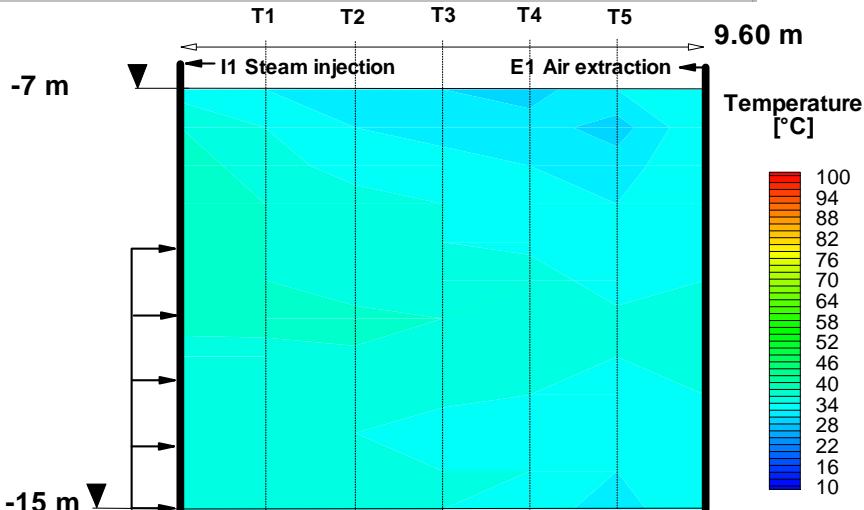

Evaporation of TCE

2002 NATO/CCMS Pilot Study Meeting Rome

Temperature Distribution – August 2002

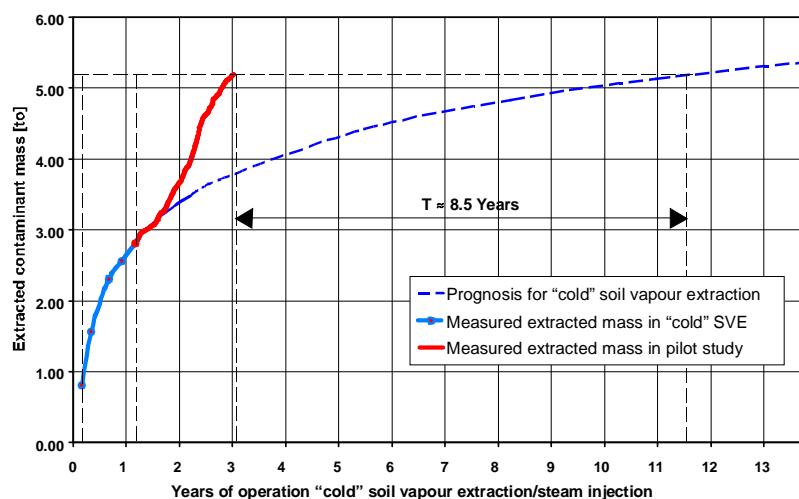

2002 NATO/CCMS Pilot Study Meeting Rome

Comparison Pilot Study / Conventional SVE

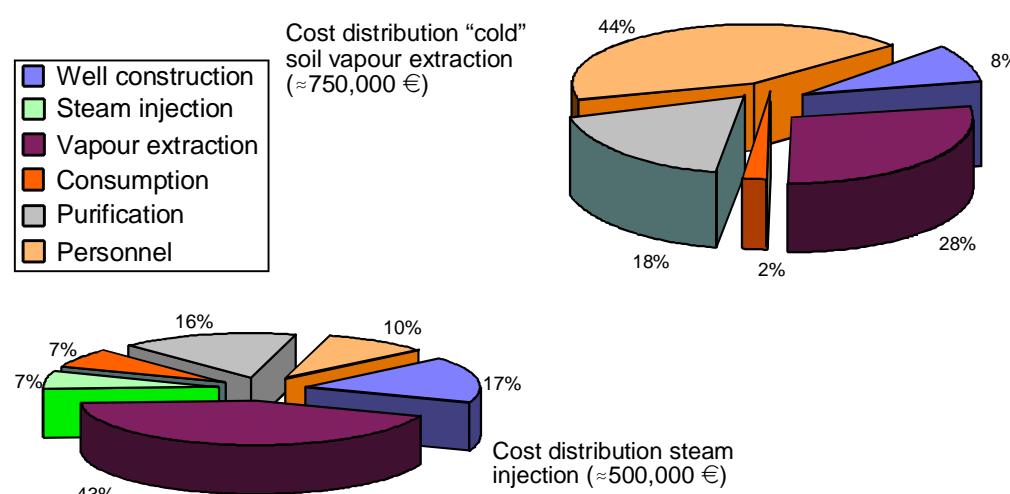

Estimated time saving:
8.5 years

2002 NATO/CCMS Pilot Study Meeting Rome

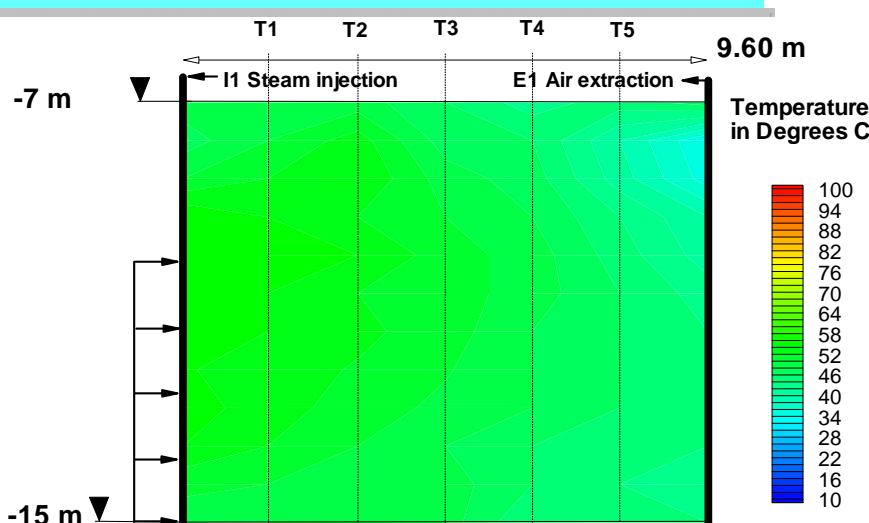

Costs for Pilot Study / SVE

2002 NATO/CCMS Pilot Study Meeting Rome

Temperature Distribution – Recent Situation

2002 NATO/CCMS Pilot Study Meeting Rome

Summary and Conclusions

- **Difficult conditions for steam injection**
 - Low permeability of the subsurface
 - Contaminant denser than water (DNAPL)
- **Measures**
 - Minimization of water input
 - Use of intermittent steam injection
- **Recent situation**
 - Cooling process not yet finished

2002 NATO/CCMS Pilot Study Meeting Rome

Summary and Conclusions

- **Difficult conditions for steam injection**
 - Low permeability of the subsurface
 - Contaminant denser than water (DNAPL)
- **Measures**
 - Minimization of water input
 - Use of intermittent steam injection
- ➡ **Economic remediation of 2.8 tons of TCE under difficult conditions was possible**

2002 NATO/CCMS Pilot Study Meeting Rome

The End

Thanks for your attention

Any questions ??
